<u>Project: Diamond Prices</u>

Complete each section. When you are ready, save your file as a PDF document and submit it here: https://classroom.udacity.com/nanodegrees/nd008/parts/235a5408-0604-4871-8433-a6d670e37bbf/project#

Step 1: Understanding the Model

Answer the following questions:

1. According to the model, if a diamond is 1 carat heavier than another with the same cut, how much more should I expect to pay? Why?

   Price = -5,269 + 8,413 x Carat + 158.1 x Cut + 454 x Clarity
   The price will be higher than the other by 8,413

2. If you were interested in a 1.5 carat diamond with a **Very Good** cut (represented by a 3 in the model) and a **VS2** clarity rating (represented by a 5 in the model), how much would the model predict you should pay for it?

   Price = -5,269 + 8,413 x Carat + 158.1 x Cut + 454 x Clarity
   Price = -5,269 + 8,413 x 1.5 + 158.1 x 3 + 454 x 5 =10094.8

Step 2: Visualize the Data

Make sure to plot and include the visualizations in this report. For example, you can create graphs in Excel and copy and paste the graphs into this Word document.

1. Plot 1 - Plot the data for the diamonds in the database, with carat on the x-axis and price on the y-axis.
2. Plot 2 - Plot the data for the diamonds for which you are predicting prices with carat on the x-axis and predicted price on the y-axis.
   o **Note**: You can also plot both sets of data on the same chart in different colors.

Carat vs Price
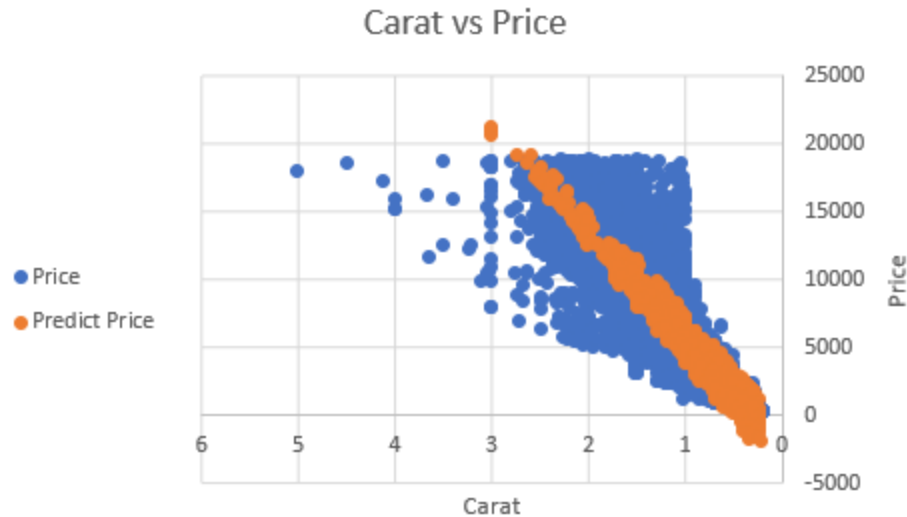

This chart contains both plots <mark>the first represented in bule and the second in orange.</mark>

What strikes you about this comparison? After seeing this plot, do you feel confident in the model's ability to predict prices?

The predicted prices are more compact than the actual data is. This is because we are not accounting for everything that effects prices. There are many more things than carat that effect it. We had Clarity and Cut(quality) factored into our formula but not even that will account for all the variation. For instance, this formula might look very different depending on the city you are training the model on.

After looking at this plot the model appears on average to predict the prices ok, but it can be very off for certain diamonds. There appears to be an outlier diamond with only 3 carats but sold for almost $20,000.00 and the does not have high quality nor high clarity.

While the formula may not be accurate for an individual diamond, it should do a decent job at predicting the price <mark>we should pay for the 3,000 diamonds at once since it on average looks representative.</mark>

Step 3: Make a Recommendation

Answer the following questions:

1. What price do you recommend the jewelry company to bid? Please explain how you arrived at that number.

I recommend a bid of $8213465.932. I arrived at this number by using a formula from the regression model provided that was based on previous diamond sales and applied it to the diamond that the company want to buy. The company generally purchases diamonds from distributors at 70% of that price, so I multiply the predicted amount 11733522.76 by 0.70 to get the final predicted bid of $8213465.932
